Types of Quadrilaterals

Introduction to Curves A **curve** is a geometrical figure obtained when a **number of points** are joined without **lifting** the pencil from the paper and **without retracing** any portion. It is basically a **line** which **need not be straight**.

The various types of curves are:

- Open curve: An **open curve** is a curve in which there is **no path** from any of its point to the **same point**.
- Closed curve: A **closed curve** is a curve that forms a **path** from any of its point to the **same point**.

A curve can be :

- A closed curve

- an open curve

- A closed curve which is not simple

Polygons: A simple **closed curve** made up of only **line segments** is called a **polygon**. Various examples of polygons are Squares, Rectangles, and Pentagons etc.

Note:

The sides of a polygon do not cross each other.

For example, the figure given below is not a polygon because its sides cross each other.

Classification of Polygons on the Basis of Number of Sides / Vertices

Polygons are classified according to the number of sides they have. The following lists the different types of polygons based on the number of sides they have:

- When there are three sides, it is **triangle**
- When there are four sides, it is **quadrilateral**
- When there are five sides, it is **pentagon**
- When there are six sides, it is **hexagon**
- When there are seven sides, it is **heptagon**
- When there are eight sides, it is **octagon**
- When there are nine sides, it is **nonagon**
- When there are ten sides, it is **decagon**

A **diagonal** is a line segment connecting two **non-consecutive vertices** of a **polygon**.

In the above figure, PR and QS are the diagonals.

Polygons on the Basis of Shape

Polygons can be classified as **concave** or **convex** based on their shape.

- A **concave** polygon is a polygon in which at least one of its **interior angles is greater than 90°** . Polygons that are **concave** have at least **some portions of their diagonals** in their **exterior**.
- A **convex** polygon is a polygon with all its **interior angle less than 180°** . Polygons that are **convex** have **no portions** of their **diagonals** in their **exterior**.

Convex polygon

Concave polygon

Classification of Polygons based on their shape.

Polygons on the Basis of Regularity

Polygons can also be classified as **regular polygons** and **irregular polygons** on the basis of regularity.

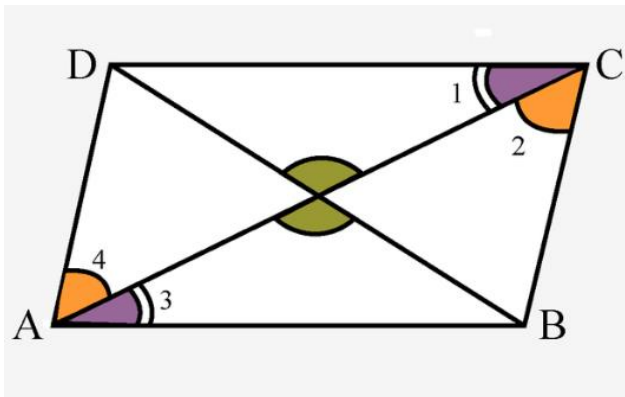

- When a polygon is both **equilateral** and **equiangular** it is called as a regular polygon. In a regular polygon, all the sides and all the angles are equal. Example: Square
- A polygon which is not regular i.e. it is not equilateral and equiangular, is an irregular polygon. Example: Rectangle

Introduction to Quadrilaterals

Angle Sum Property of a Polygon

According to the **angle sum property** of a polygon, the **sum of all the interior angles** of a polygon is equal to $(n-2) \times 180^\circ$, where n is the number of sides of the polygon.

Division of a quadrilateral into two triangles.

As we can see for the above quadrilateral, if we join one of the diagonals of the quadrilateral, we get two triangles.

The sum of all the interior angles of the two triangles is equal to the sum of all the interior angles of the quadrilateral, which is equal to $360^\circ = (4-2) \times 180^\circ$.

So, if there is a polygon which has n sides, we can make $(n - 2)$ **non-overlapping triangles** which will perfectly cover that polygon.

The **sum of the interior angles of the polygon** will be equal to the **sum of the interior angles of the triangles** = $(n-2) \times 180^\circ$

Sum of Measures of Exterior Angles of a Polygon

The **sum** of the measures of the **external angles** of any **polygon** is **360°** .

The classification of quadrilaterals are dependent on the nature of sides or angles of a quadrilateral and they are as follows:

- Trapezium
- Kite
- Parallelogram
- Square
- Rectangle
- Rhombus

For More Information On Types Of Quadrilaterals, Watch The Below Videos.

Trapezium: A trapezium is a quadrilateral with a **pair of parallel** sides.

Parallelogram: A **parallelogram** is a quadrilateral whose opposite sides are **parallel** and **equal**.

Rhombus

- A **rhombus** is a quadrilateral with **sides** of **equal length**.
- Since the **opposite sides** of a rhombus have the **same length**, it is also a **parallelogram**.
- The **diagonals** of a **rhombus** are **perpendicular bisectors** of one another.

Properties of Parallelograms

For More Information On Properties Of Parallelogram, Watch The Below Video.

Elements of a Parallelogram

- There are **four sides** and **four angles** in a parallelogram.
- The **opposite sides** and **opposite angles** of a parallelogram are **equal**.
- In the parallelogram ABCD, the sides AB and CD are **opposite sides** and the sides AB and BC are **adjacent sides**.
- Similarly, $\angle ABC$ and $\angle ADC$ are **opposite angles** and $\angle ABC$ and $\angle BCD$ are **adjacent angles**.

Angles of a Parallelogram

The **opposite angles** of a parallelogram are **equal**.

In the parallelogram ABCD, $\angle ABC = \angle ADC$ and $\angle DAB = \angle BCD$.

The **adjacent angles** in a parallelogram are **supplementary**.

\therefore In the parallelogram ABCD, $\angle ABC + \angle BCD = \angle ADC + \angle DAB = 180^\circ$

Diagonals of a Parallelogram

The **diagonals** of a parallelogram **bisect** each other at the point of intersection.

In the parallelogram ABCD given below, $OA = OC$ and $OB = OD$.

Properties of Special Parallelograms

Rectangle

A **rectangle** is a **parallelogram** with **equal angles** and each angle is **equal to 90°** .

Properties:

- **Opposite sides** of a rectangle are **parallel** and **equal**.
- The length of **diagonals** of a rectangle is **equal**.
- All the **interior angles** of a rectangle are **equal to 90°** .
- The **diagonals** of a rectangle **bisect** each other at the point of intersection.
